ESTIMATE OF POTENTIALLY HIGH OZONE CONCENTRATIONS AREAS IN THE CENTER OF THE IBERIAN PENINSULA

Magdalena Palacios, Fernando Martín, Begoña Aceña, Abdessalam Zarougui and Carmen Córdoba.

Research Center on Energy, Environment and Technology (CIEMAT), Madrid, Spain.
INTRODUCTION (1)

- The Greater Madrid Area (GMA) is located in the centre of the Iberian Peninsula.
- Huge source of ozone precursors.
- Intense formation of tropospheric ozone in summer time, late spring and early autumn.
INTRODUCTION (2)

Recent European directives, air pollution modelling is a very important tool for many the air quality management:
- air quality assessment,
- design of plans and programs for air pollution abatement
- design of networks for air quality monitoring. Furthermore,

Development of ozone control strategies requires analysing ozone response to variations in precursors emissions considering a wide range of realistic meteorological conditions.
INTRODUCTION (3)

Previous simulations (TVM model coupled to transport/chemistry module) for two different summer ozone episodes in GMA:

- High levels of ozone, above the population information threshold and close to the alert threshold areas 100 km far away from Madrid city
- Confirmed by observations (validated model)
- Need of forcing to the reduction of not only traffic road but also total anthropogenic emissions to comply with standard levels.
OBJECTIVE

To study of which areas could be potentially affected by high ozone levels in the centre of the Iberian Peninsula by using an evaluated model.
METHODOLOGY

1. Set up of meteorological scenarios.
2. Simulations of the photochemical air pollution for the meteorological scenarios.
3. Analysis of the simulated spatial patterns of ozone concentration distribution.
Meteorological scenarios (1)

- Period for selecting meteorological scenarios from mid April to mid October.
- 1992 and 1995 (each year treated separately).
- Days with rain or overcast was removed.
- Selected variables representing the atmosphere state every day:
  - Surface and 850-HPa-level wind speed (ventilation).
  - Surface air temperature (important for ozone formation).
  - Temperature gradient between 850 HPa level and surface (atmospheric stability).
- Cluster analysis (k-means technique) was used in order to group days with similar meteorological state.
- All data were previously normalised.
3 significant cluster resulted from every year

- Cluster 1 (3% and 4% of the studied days in 1992 and 1995).
  - higher-than-average winds,
  - high temperatures (less high in 1995)
  - little atmospheric instability
- Cluster 2 (63% -1992-, 77% -1995-)
  - very weak winds,
  - high temperatures
  - higher atmospheric instability,
- Cluster 3 (34% -1992-, 19% -1995-)
  - weak winds
  - temperatures are even higher than former cases.
Meteorological scenarios (3)

- Wind direction (850 HPa) was not used in cluster analysis because of its circular features.
- For setting up the meteorological scenarios representing every cluster, a sub classification was done based on wind direction (analysis of frequency - histograms).
- The selected meteorological scenarios were determined as the day being closest to the mean state of every sub cluster.
- 9 representative days (scenarios) for every reference year were used in simulations (65% correspond to summer time).
- TVM models was used for air flows simulations.

Simulations of photochemical air pollution

Model description

- Meteorological model used was the Topographic Vorticity Mesoscale (TVM) model (Thunis and Clappier, 2000).
- Evaluated for the same domain (Martín et al., 2001a, 2001b).
- Meteorological model is coupled to a transport/chemistry module based on the CIT model (McRae et al., 1983) and updated by Harley et al. (1993).
- Operator splitting technique by which advection is integrated separately from the diffusion/chemistry.
- Highly accurate and computational efficient hybrid scheme Gong and Cho (1993) for solving the chemical system of RACM mechanism (Stockwell et al., 1997).
- TVM+RACM has simulated satisfactory ozone pollution episodes taking place in this region (Palacios, 2001; Palacios et al., 2002b).
Simulations of photochemical air pollution

Meteorological model setup

- Meteorological domain corresponds to a geographical area of 360x300 km² in the center of the Iberian Peninsula.
- Non-regular or stretched grid with variable resolution considering 64x54 grid points.
- Spatial resolution is maximum at its center (5x5 km²), coinciding with the area selected to run the photochemical model.
- Capture the atmospheric flows and to reproduce the main mesoscale circulations characteristics.
- Terrain following coordinate system with 24 levels, the lowest of them at 20 m above the ground and a maximum of 1000 m.
- Top of the domain at 15400 m.
- Simulations cover 37 hours starting at 1200 UTC.
Simulations of photochemical air pollution
Photochemical model setup

- A different grid than that for meteorology was used to run the transport/chemical module.
- Photochemical modeling domain is 270x200 km²
- Regular resolution of 5x5 km² coinciding with the area of maximum resolution of the TVM model.
- 54x40 grid points in horizontal
- 8 in the vertical up to 4400 m above the ground.
- Simulations cover 37 hours starting at 1200 UTC.
- Emission data resulted from a Top-Down methodology (Palacios and Martín, 2002):
  - Spatial disaggregation to 5x5 Km cells.
  - Time disaggregation ➔ hourly.
  - VOC speciation (18 species) by Loibl et al. (1993)
RESULTS
Analysis of simulated flow patterns.

- Very notable air flow cycles.
- Mesoscale wind flows are strongly driving by the synoptic forcing.
- In many cases, surface winds have the same direction than those of synoptic.
RESULTS

Analysis of the simulated patterns of ozone concentration (1)

Four Ozone concentration patterns:

- **Type A**: The whole Community of Madrid
- **Type G**: Sierra del Guadarrama (Northwest)
- **Type N**: Sierra de Ayllón (North)
- **Type E**: East from Madrid metropolitan area.
Type A

Julian day 186. Year: 1995. Hour: 16 UTC.

HARMO 9 - Garmisch Partenkirchen, Germany
Type G

Julian day 173. Year: 1995. Hour: 16 UTC.

HARMO 9 - Garmisch-Partenkirchen, Germany
Type N

Type E

(ppb)

300 350 400 450 500 550

0 5 6.5 10 15 30 45 55 70 80 90 100 110 120 130 140 150 160

RESULTS
Analysis of the simulated patterns of ozone concentration (4)

- Not very high ozone levels ➔ strong winds and low isolation
- Very high ozone levels ➔ weak winds and high isolation.
- High concentrations areas related to the synoptic wind forcing on the diurnal wind flow cycle.
- Frequently, high concentrations areas are 100 Km away from city.
  - Type N (affecting North area) ➔ 61%
    • Maximum average (104 ppb) but large variability in ozone levels (81-121 ppb).
  - Type G (affecting Northwest area) ➔ 18%
    • Maximum average (117 ppb), variability (104-126 ppb)
  - Type A (affecting almost all Community of Madrid) ➔ 12%
    • Maximum average (129 ppb) with a record of 149 ppb.
  - Type E (affecting East area) ➔ 9%
    • Maximum average (107 ppb), variability (91-112 ppb)
